

**City of Philadelphia
Department of Public Health
Air Management Services**

Philadelphia's Air Quality Report 2022

Executive Summary¹

This report focuses on the air quality of the City of Philadelphia, as presented by the Philadelphia Department of Public Health, Air Management Services, the local air pollution control agency for the City of Philadelphia. As an urban area, Philadelphia faces many of the same pollution challenges as other densely populated areas, such as emissions from vehicles and industries. The information contained in this report reviews Philadelphia's air quality for the calendar year 2022 and reports how the City's air compared with the National Ambient Air Quality Standards (NAAQS). This report covers the following criteria pollutants: **ozone, carbon monoxide, nitrogen dioxide, sulfur dioxide, particulate matter, and lead**. It also provides an overview of **hazardous air pollutants (HAPs)**, also referred to as **air toxics**.

In general, trends show many air pollutants in Philadelphia to be decreasing. In 2022, Philadelphia attained the NAAQS for all pollutants, except for ozone. There were 228 good days, 133 moderate days, and 4 unhealthy days (3 from Code Orange ozone and 1 from Code Orange PM_{2.5}) in Philadelphia.

In 2022, AMS continued the Philadelphia Air Quality Survey. This project has 48 street level, neighborhood-oriented air sampling sites throughout the City to sample the ambient air for PM_{2.5}, PM_{2.5} speciation, NO₂, SO₂, and O₃.

For further information, please visit the Air Management Services website at: <https://www.phila.gov/departments/department-of-public-health/about-us/contact-us/> or contact us at: 215-685-7580.

Introduction

The Philadelphia Department of Public Health, Air Management Services (AMS) is responsible for the prevention, abatement, and control of air pollution and air pollution nuisances; achieving and maintain the National Ambient Air Quality Standards (NAAQS) in Philadelphia; and protecting the health and quality of life of the Philadelphia community from the adverse effects of air contaminants and noise.

AMS implements the environmental protection mandates contained in city, state, and federal regulations; reviews construction and operating permits for compliance with air regulations, standards, and guidelines; develops emission inventories for large stationary sources; operates and maintains a citywide air sampling network to continuously monitor Philadelphia's air; routinely inspects pollution sources; services citywide complaints of air pollution, asbestos, and noise; issues violations; conducts enforcement actions; and advances voluntary emissions reductions.

Air Monitoring Network

The City of Philadelphia is served by a network of ten air monitoring sites located throughout the City that measure the criteria pollutants: ozone (O₃), carbon monoxide (CO), nitrogen dioxide (NO₂), sulfur dioxide (SO₂), particulate matter (PM₁₀ and PM_{2.5}), and lead (Pb). Four of the sites also measure air toxics, such as formaldehyde, benzene, and carbon tetrachloride. Many of the measurements are made in "real time", meaning that the measurements show pollution levels as they occur, instead of after the fact. The map on Page 6 shows the location of air monitors and the pollutants measured at each monitoring location. AMS measures air quality for several reasons:

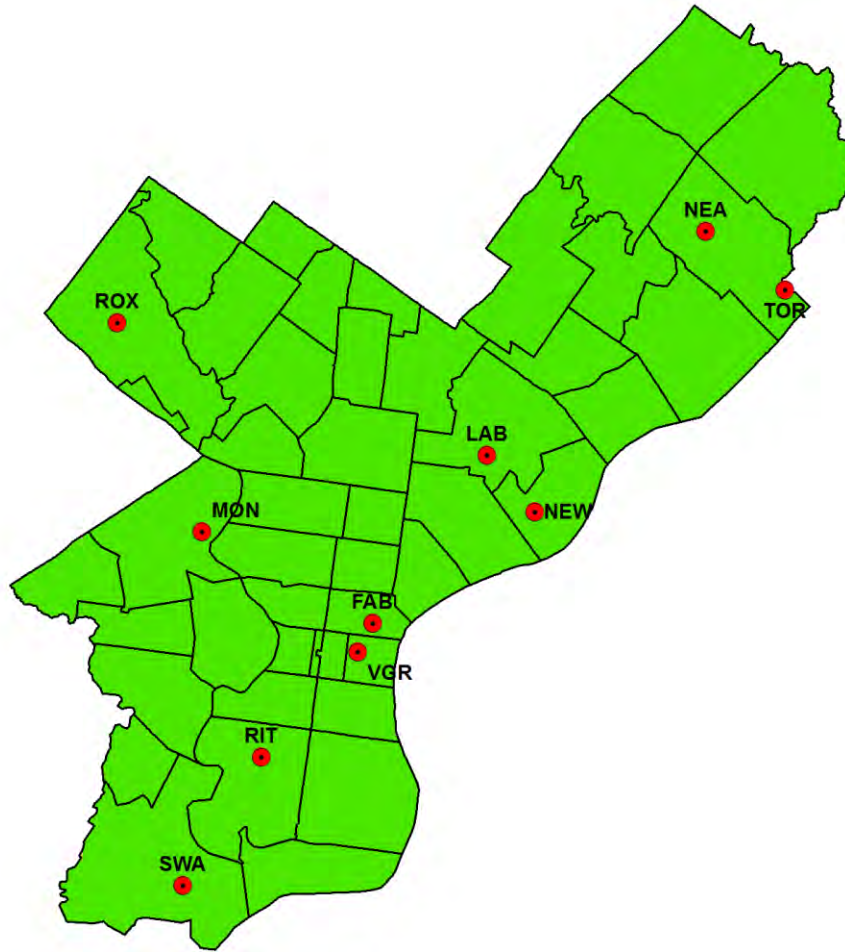

- To ensure that long-term goals and targets to reduce levels of air pollution are being met.
- To provide information to the public as to how good or bad the air quality is in Philadelphia.
- To ensure attainment with standards set forth by the United States Environmental Protection Agency (EPA).

An air monitoring network plan (AMNP) has been made available to the public annually starting in the year 2007. The most recent AMNP is located on the AMS reports and documents website:

<https://www.phila.gov/documents/air-management-reports-and-documents/>.

This monitoring network is designed and established following requirements and protocols set forth by EPA, specified in Title 40 Part 58 of the Code of Federal Regulations.

Table 1 – Site Summary Table

AMS Site	Address	Statement of Purpose
LAB	1501 E. Lycoming St	Built in 1964, this monitor assesses the City’s impact on ozone precursors and is a designated Photochemical Assessment Monitoring Station (PAMS) site. New monitoring methods are often evaluated on this site.
ROX	Eva St & Dearnley St	As a periphery site, this site is used for measuring Air Toxics and Carbonyls.
NEA	Grant Ave & Ashton Rd	As a periphery site, this site is best for measuring ozone in the City, because as a secondary pollutant, ozone requires some time to form (longer time periods allow precursor emissions to distribute more uniformly across a region, and thus allow ozone concentrations to develop more uniformly across subregions and even large-scale regions). We tend to see fewer “hot spots” as ozone is not directly emitted from combustion activities as other pollutants are.
NEW	2861 Lewis St	This site was one of the few sites that was originally established to measure the impact of specific industrial facilities which are now closed. Today, the monitors conduct continuous particulate monitoring and provide information about the nearby wastewater treatment plant. As of October 2, 2013, the NCore site has been moved to this site from Baxter water treatment plant (BAX).
RIT	24 th St & Ritner St	This site was selected to help assess the impact of the petroleum refinery on the local community. The area was identified by air quality modeling.
FAB	3 rd St & Spring Garden St	This site was established to monitor high levels of fine particulates in the City based on EPA Region III’s air quality modeling of air toxics in Philadelphia. It shows high levels of fine particulate created by vehicle traffic.
SWA	8200 Enterprise Ave	This site was established to measure toxics, carbonyls, and metals. Fine particulates may also be monitored. EPA Region III modeling analysis has shown that areas near the airport have high levels of aldehydes.
TOR	4901 Grant Ave & James St.	This site was established as the 1 st near-road NO ₂ monitor in the Philadelphia-Camden-Wilmington, PA-NJ-DE-MD Metropolitan Statistical Area.
MON	I-76 & Montgomery Drive	This site was established as the 2 nd near-road monitor in the Philadelphia-Camden-Wilmington, PA-NJ-DE-MD Metropolitan Statistical Area.
VGR	6 th St & Arch St	EPA’s Village Green Air Monitoring Station. Utilizes solar and wind turbine power as energy sources. Sited to increase community awareness of environmental conditions.

Quality Assurance

The Air Management Services Laboratory's main responsibility is to provide accurate data on the quality of the City's air, as it can lead to various health concerns. Pollutants in the atmosphere are measured to answer several questions such as:

- Are the National Ambient Air Quality Standards being met in Philadelphia?
- How close or how far away are we from achieving the projected goals for these standards?
- Which pollutants are getting worse (increasing in concentration) or improving (decreasing in concentration)?

Many of our measurements require detecting very small amounts of a pollutant, often expressed as parts per million (ppm) or parts per billion (ppb). An illustration: imagine a million yellow balls, all the same size, with several red balls in the middle of them; we would need to find those red balls and then be able to count them. The instruments used to measure air pollutants need to be reliable in identifying the pollutant and accurate in making the measurement every time. The primary way we check to see if our instruments are giving accurate measurements is to send a sample of air which has a known amount (concentration) of a pollutant and compare the instrument's concentration measurement to what we know is the correct concentration. Adjustments (calibration) can then be made to an instrument to give a better measurement. If the equipment is off by a significant margin, the instrument needs to be repaired or replaced. The EPA and our Laboratory have standard operating procedures on how accurate and reliable measurements need to be to answer the questions being asked. The instruments being used now are much more reliable than those available many years ago. Steps to assure good data quality include:

- Automated calibration,
- Manual calibration conducted by chemists,
- Review of the data by an experienced QA engineer or scientist.

The system is geared towards public safety; for example, a few measurements can be enough to identify a problem in meeting the NAAQS, but many good measurements over a period of time (often three years) as well as additional types of analysis are needed to "demonstrate compliance" with the corresponding pollutant's standard on the NAAQS.

The EPA's regulations on establishing an air monitoring network are found in Title 40 – Protection of Environment in the Code of Federal Regulations Part 58 – Ambient Air Quality Surveillance². A comprehensive technical systems audit (TSA) by EPA occurs at least once every three years to evaluate an ambient air quality monitoring program. AMS' last TSA occurred September 2021 and is expected again in 2023. The TSA included on-site interviews with program personnel, evaluations of ambient air monitoring sites and

² https://www.ecfr.gov/cgi-bin/text-idx?SID=af0f262c08e4f8aad56a91c70e0ce294&mc=true&tpl=/ecfrbrowse/Title40/40cfr58_main_02.tpl

laboratories operated by the agency, and a review of quality assurance and data processing procedures. AMS follows EPA's guidance in the Quality Assurance Handbook for Air Pollution Measurement Systems, Volume II³, dedicated to the Ambient Air Quality Surveillance Program and the data collection activities inherent to that program. Additionally, workshops are provided annually to staff as an opportunity to interact with and learn from nearby state and local monitoring agency program representatives as well as expert speakers. Participants share experiences meeting challenges with new air quality monitoring technology, updated data analysis and quality assurance methods, and revised regulatory requirements. AMS staff regularly attend trainings and workshops held by the Mid-Atlantic Regional Air Management Association (MARAMA), which can be found on the MARAMA website⁴.

Air Quality Index

The Air Quality Index (AQI) is a color-coding system for air quality used by government agencies across the United States. Daily pollution levels for five pollutants (ground-level ozone, particulate matter, carbon monoxide, sulfur dioxide, and nitrogen dioxide) are converted into a score ranging from 1 to 500. A level of 101 generally corresponds to the National Ambient Air Quality Standard for each pollutant, and an “Action Day” occurs when the AQI for any pollutant exceeds 100. The color coded AQI is shown in Figure 2.1.

Figure 2.1 – Color Coded AQI

Action days are more likely to occur in the summer months but can happen any time of the year. On these days, the public is advised to take precautions to protect themselves and their families from health effects and do their part to reduce pollution. For example, on a Code Orange day, children, seniors, and those with respiratory ailments (sensitive groups) are advised to minimize prolonged outdoor exposure. On a Red or Purple day, all residents are advised to limit outdoor activity. Red and purple days are uncommon. The highest of the five pollutant scores is reported as the overall air quality rating for Philadelphia for a given day. The daily AQI values for 2022 are shown in Figure 3.⁵

Action Days are reported through print, radio, television, online media, and by local and regional air agencies. Current air quality conditions in Philadelphia can be found on the website: <https://www.phila.gov/services/mental-physical-health/environmental-health-hazards/air-quality/>.

⁵ <https://www.epa.gov/outdoor-air-quality-data/air-data-tile-plot>. Downloaded July 21, 2023.

Figure 3.2 shows the annual summary of the number of good, moderate, and unhealthy air quality days in Philadelphia based on monitoring conducted by AMS since 1990⁶. The chart has been standardized with the current EPA AQI breakpoints or pollutant concentration cut-offs and are consistent with the 2015 ozone standards.

Figure 3.1 – Daily AQI Values for 2022

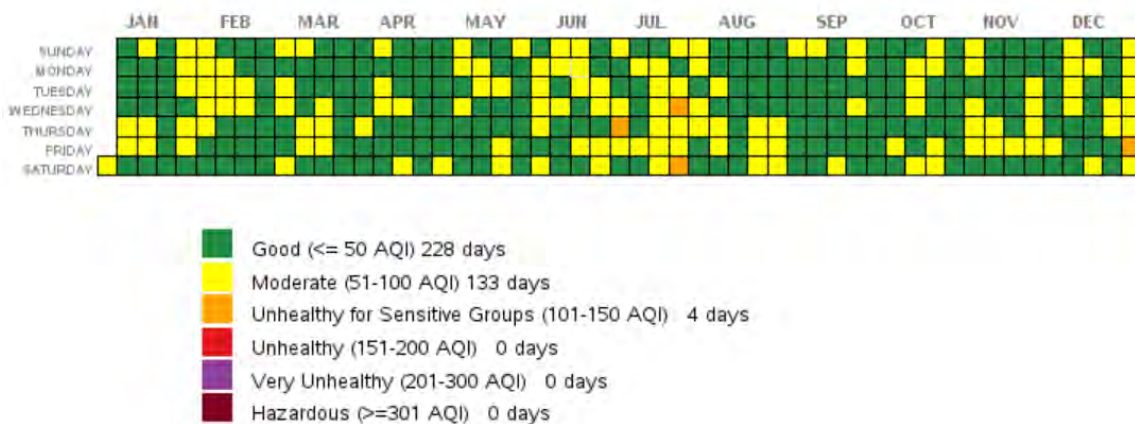

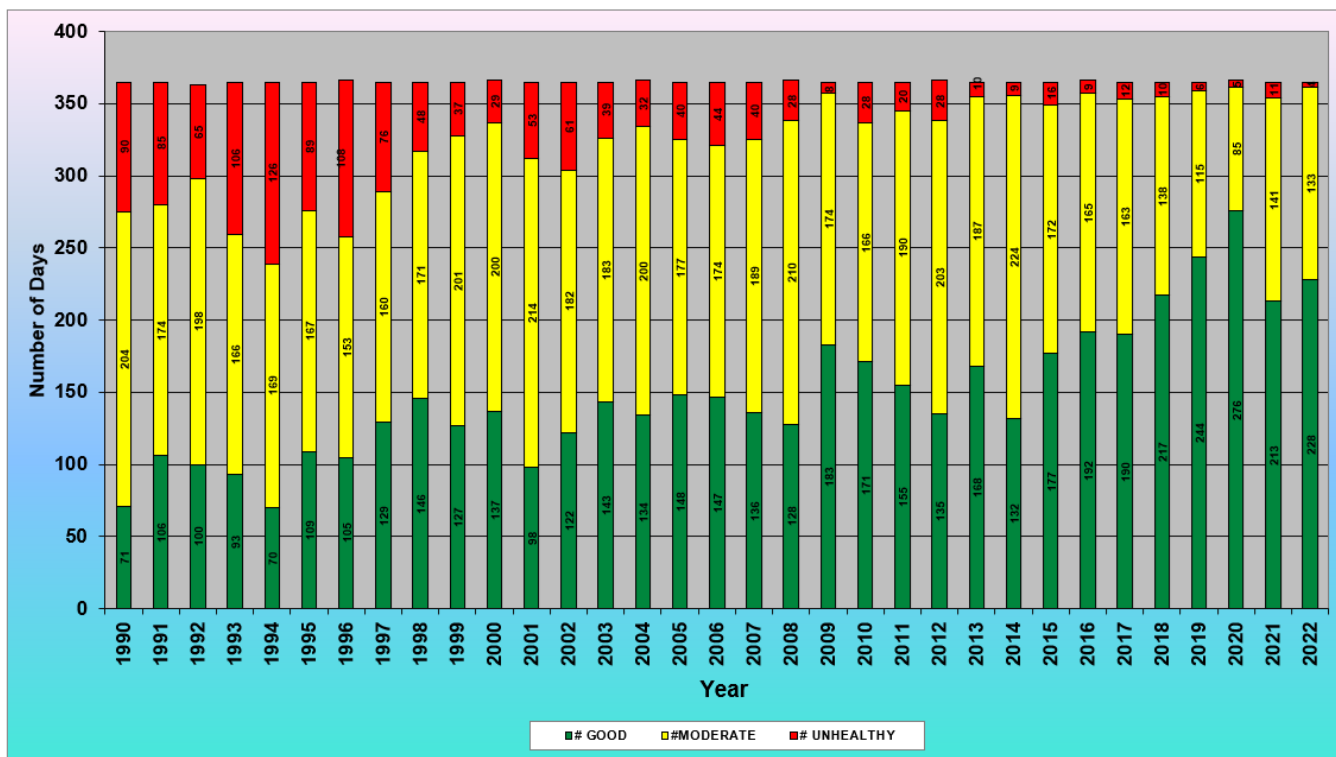

Figure 3.2 – Philadelphia Annual AQI Summary
(Red color indicates Code Orange, Code Red and worse air quality days combined)

⁶ <https://www.epa.gov/outdoor-air-quality-data/air-quality-index-report>. Downloaded July 21, 2023.

National Ambient Air Quality Standards

The Clean Air Act (CAA), which was last amended in 1990, requires EPA to set NAAQS for pollutants considered harmful to public health and the environment. The CAA identifies two types of national ambient air quality standards. Primary standards provide public health protection, including protecting the health of "sensitive" populations such as asthmatics, children, and the elderly. Secondary standards provide public welfare protection, including protection against decreased visibility and damage to animals, crops, vegetation, and buildings.

The EPA has set NAAQS for six criteria air pollutants: carbon monoxide, sulfur dioxide, nitrogen dioxide, lead, particulate matter ("dust" or "soot"), and ozone. Periodically, the standards are reviewed and may be revised. The current standards are listed here: <https://www.epa.gov/criteria-air-pollutants/naqs-table>. A history of the standard for each criteria pollutant is shown in Appendix C. Units of measure for the standards are parts per million (ppm) by volume, parts per billion (ppb) by volume, and micrograms per cubic meter of air ($\mu\text{g}/\text{m}^3$).

In 2022, Philadelphia was in attainment for all criteria pollutants, except for ozone.

The Pollutants We Measure

The following pages provide information on the health effects, sources, and trends of pollutants measured in Philadelphia. Included are the six pollutants, commonly called criteria pollutants, for which EPA has established NAAQS, as well as pollutants identified as being toxic or hazardous. Each of the criteria pollutants is graphed to show the historical trends compared with national standards. The graphs identify the range of values ("MIN / MAX RANGE") and with a solid black line, the mean of all recorded levels. It is important to note the mean, as it factors out extreme levels, and thereby provides a better indication of general air quality levels. In addition, Appendix B provides tables of historical data downloaded from EPA's Air Quality System data mart.

Ozone (O₃)

NAAQS:

- The 3-year average of the annual fourth-highest daily maximum 8-hour average O₃ concentration is less than or equal to 0.070 ppm

Figure 4.1 – Ozone Monitoring Map

Ground level ozone (the primary constituent of smog) is the pollutant most often responsible for unhealthy air quality in the Philadelphia region. Ozone is not emitted into the atmosphere directly but is formed by chemical reactions between other pollutants. Specifically, Volatile Organic Compounds (VOCs) and Nitrogen Oxides (NO_x) react to create ozone in the presence of heat and sunlight. Ozone levels are consistently higher during the summer months.

VOCs are organic (i.e., carbon-containing) compounds that evaporate readily, such as gasoline vapors and paint fumes. NO_x stands for two compounds, nitric oxide (NO) and nitrogen dioxide (NO₂). Some VOCs are considerably more reactive in the atmosphere than others, and the reactivity of a VOC influences how quickly ozone forms. A compound that reacts in a few minutes to produce ozone will have a much greater impact near its source than one that reacts more slowly. Thus, ozone can form at various distances downwind of a VOC source due to the speed of these chemical reactions.

There are four categories of emission sources from human activity that produce VOC and NO_x:

- Point sources – Large utilities, industrial facilities, and other operations.

- Nonpoint sources – Commercial, solvent use, waste disposal, and other smaller sources.
- Nonroad sources – Construction and agricultural equipment, recreational boats, lawnmowers, and other mobile sources.
- Onroad sources – Cars, trucks, buses, and motorcycles.

Figure 4.2 shows NO_x and VOC emissions from all source categories for Philadelphia County for 2020. The EPA’s 2020 National Emission Inventory (NEI) is the most recent national air emissions inventory.

Figure 4.2 – 2020 NO_x and VOC Emissions from All Sources⁷

2020 NO_x Emissions in Philadelphia (tons):

Total: 10,541			
Point	Nonpoint	Nonroad	Onroad
957.8	4,783.9	1,112.0	3,687.7
9.1%	45.4%	10.5%	35.0%

2020 VOC Emissions in Philadelphia (tons):

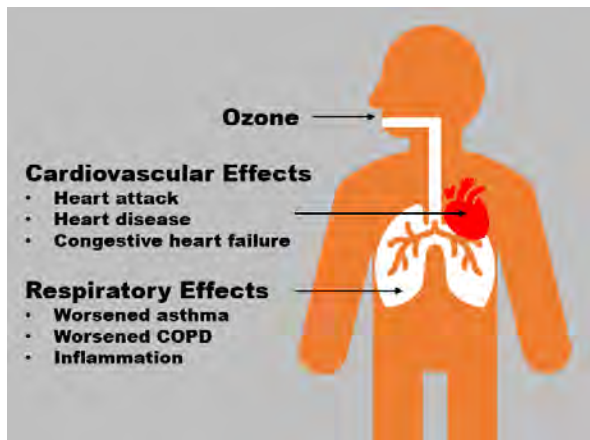

Total: 15,555			
Point	Nonpoint	Nonroad	Onroad
530.6	11,375.2	1,194.4	2,454.8
3.4%	73.1%	7.7%	15.8%

Over the years, emissions from point sources have been decreasing steadily, while nonpoint and onroad sources emit large percentages of NO_x and VOC in Philadelphia.

Emissions of VOC and NO_x may be carried by wind currents while reacting to produce high ozone levels hundreds of miles from their sources. In the eastern United States during the summer months, ground level ozone is frequently high over wide areas containing several states. This phenomenon is caused by ozone and its precursors traveling via wind currents across great distances.

In any discussion of ozone, it is important to distinguish between the effects of ozone at the ground and ozone high in the atmosphere. An advertisement might use the slogan “good up high, bad nearby,” to describe ozone. Up high, in what’s called the ozone layer (about 20 to 25 kilometers above sea level), ozone is essential to the health of nearly every living thing because it protects the Earth from harmful ultraviolet (UV) light. Near the ground, ozone reacts with buildings, plants, animals, and people, and is one of the most irritating, harmful components of smog. Smog refers to the whole mixture of air pollution in an area, and may include ozone, a whole host of other gases, as well as fine particles and the hazy conditions they cause.

⁷ www.epa.gov/air-emissions-inventories/2020-nei-supporting-data-and-summaries. Downloaded July 21, 2023.

People who are very young, the elderly, or those who have chronic lung problems such as asthma are particularly sensitive to ground level ozone. EPA concluded that ozone pollution causes respiratory harm such as worsened asthma, worsened COPD, and inflammation; may cause reproductive and developmental harm as well as harm to the central nervous system; and likely to cause cardiovascular harm such as heart attacks, heart disease, and congestive heart failure.⁸

In 2022, as seen in Figure 4.1, there were four ozone monitoring sites: LAB, NEA, NEW, and VGR. The ozone monitor at VGR is used to demonstrate the capabilities of new real-time monitoring technology using solar power for residents and citizen scientists to learn about local air quality. The real-time data is available here: <http://villagegreen.airnowtech.org/welcome?siteID=24292>. Data from the VGR monitor is not used for comparison to the NAAQS or AQI.

Figures 4.3 and 4.4 show the trends for the 8-hour ozone concentrations in Philadelphia and the design value (based on 3-year average concentrations) at the Northeast Airport site (NEA) compared with the 2015 ozone standard, respectively. The NEA monitoring site has the highest ozone design value in Philadelphia.

⁸ U.S. Environmental Protection Agency, Integrated Science Assessment for Ozone and Related Photochemical Oxidants, 2013. EPA/600/R-10/076F.

Figure 4.3 – Ozone Trends for the 4th Highest Daily Maximum 8-Hour Concentration for All Sites

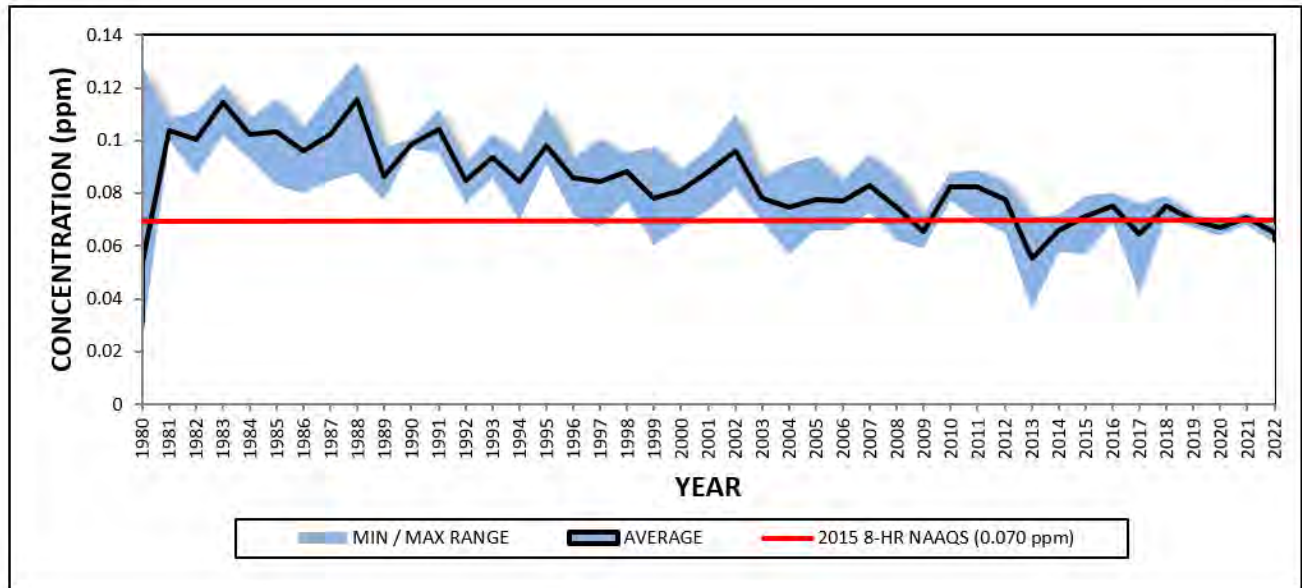

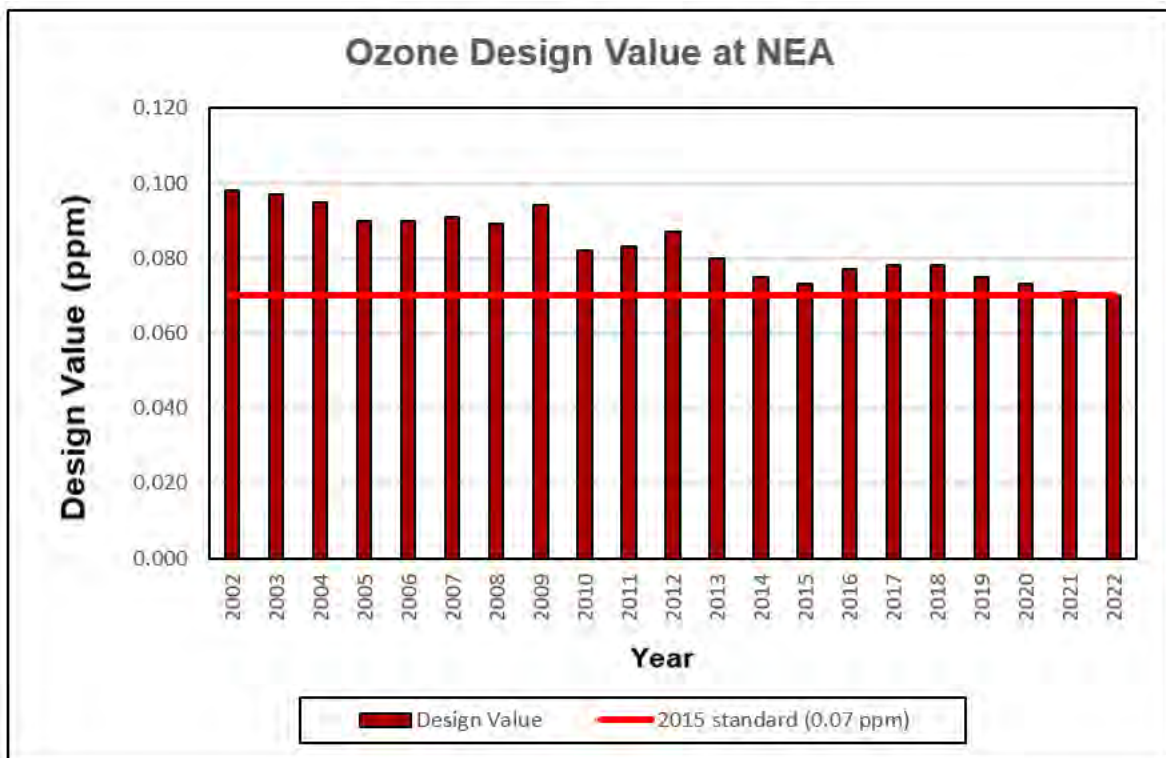

Figure 4.4 – Ozone Design Value at NEA Monitoring Site (AQS ID 421010024)

Carbon Monoxide (CO)

NAAQS:

- 9 parts per million for an 8-hour average concentration (2nd highest) not to be exceeded more than once per year.
- 35 parts per million for a 1-hour average concentration not to be exceeded more than once per year.

Figure 5.1 – CO Monitoring Map

Carbon monoxide (CO) is colorless, odorless, and at high concentrations a poisonous gas. It is formed when the carbon in fuels is not burned completely. The major source of CO is motor vehicle emissions. Other sources of CO include residential, industrial, and natural processes. Weather greatly affects CO levels, and peak CO concentrations typically occur during the colder months of the year.

Carbon monoxide enters the bloodstream and reduces oxygen delivery to the body's organs and tissues. The health threat from carbon monoxide is most serious for those who suffer from cardiovascular disease. Exposure to elevated CO levels is associated with impairment of vision, reduced work capacity, reduced manual dexterity, poor learning ability, and difficulty in performing complex tasks. At very high levels, carbon monoxide can be fatal.

Over a forty-year period, there has been a continued reduction in carbon monoxide levels. This is mainly the result of federal requirements for cleaner automobiles and fuel and state inspection/maintenance programs.

Figures 5.2 and 5.3 on the following page show the trends for the CO 8-hour concentration and 1-hour concentration, respectively, in Philadelphia.

Figure 5.2 – CO Trends for the 2nd Highest 8-Hour Average Concentration

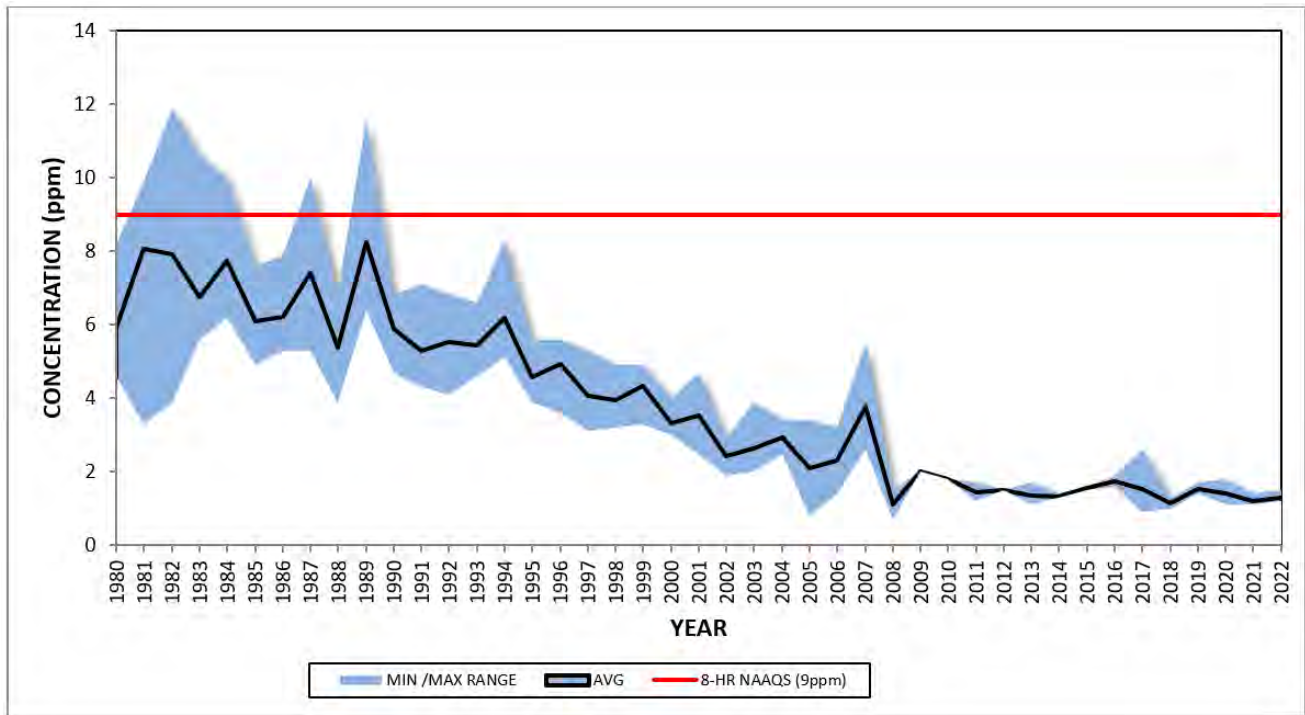

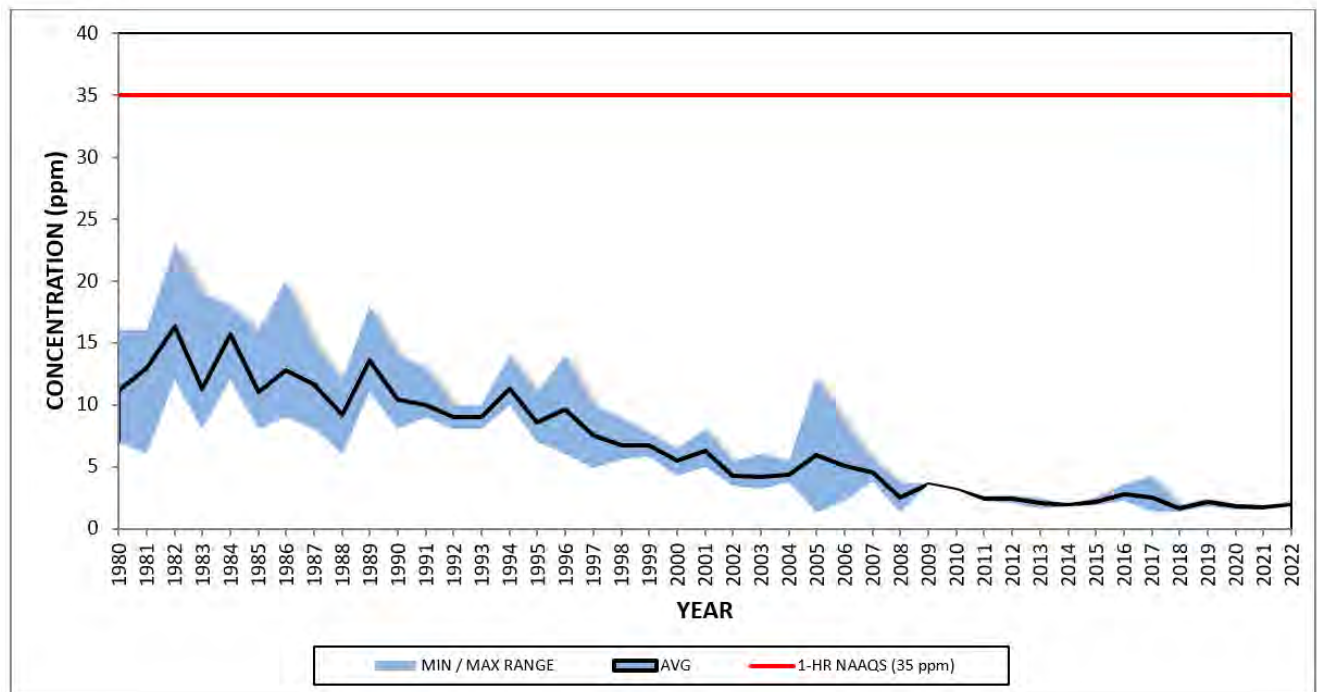

Figure 5.3 – CO Trends for the Highest 1-Hour Average Concentration

Nitrogen Dioxide (NO₂)

NAAQS:

- The annual average concentration is less than or equal to 53 ppb.
- The 3-year average of the annual 98th percentile of the daily maximum 1-hour average concentration is less than or equal to 100 ppb.

Figure 6.1 – NO₂ Monitoring Map

Nitrogen dioxide is a light brown gas that is an important component of urban haze. The compound is created primarily from fuel combustion in motor vehicles, utilities, and industrial sources.

Nitrogen dioxide can irritate the lungs and lower resistance to respiratory infections such as influenza. Nitrogen oxides (NO_x) are an important precursor to both ozone and acid rain and can affect both land and water ecosystems. They contribute to the formation of fine particulate matter, haze, and reductions in visibility.

Ambient levels of nitrogen dioxide in Philadelphia are significantly below the NAAQS, showing a sustained downward trend over time.

Figures 6.2 and 6.3 show the NO₂ trends for annual average and daily maximum of one-hour concentrations, respectively.

Figure 6.2 – NO₂ Trends for Annual Average Concentration

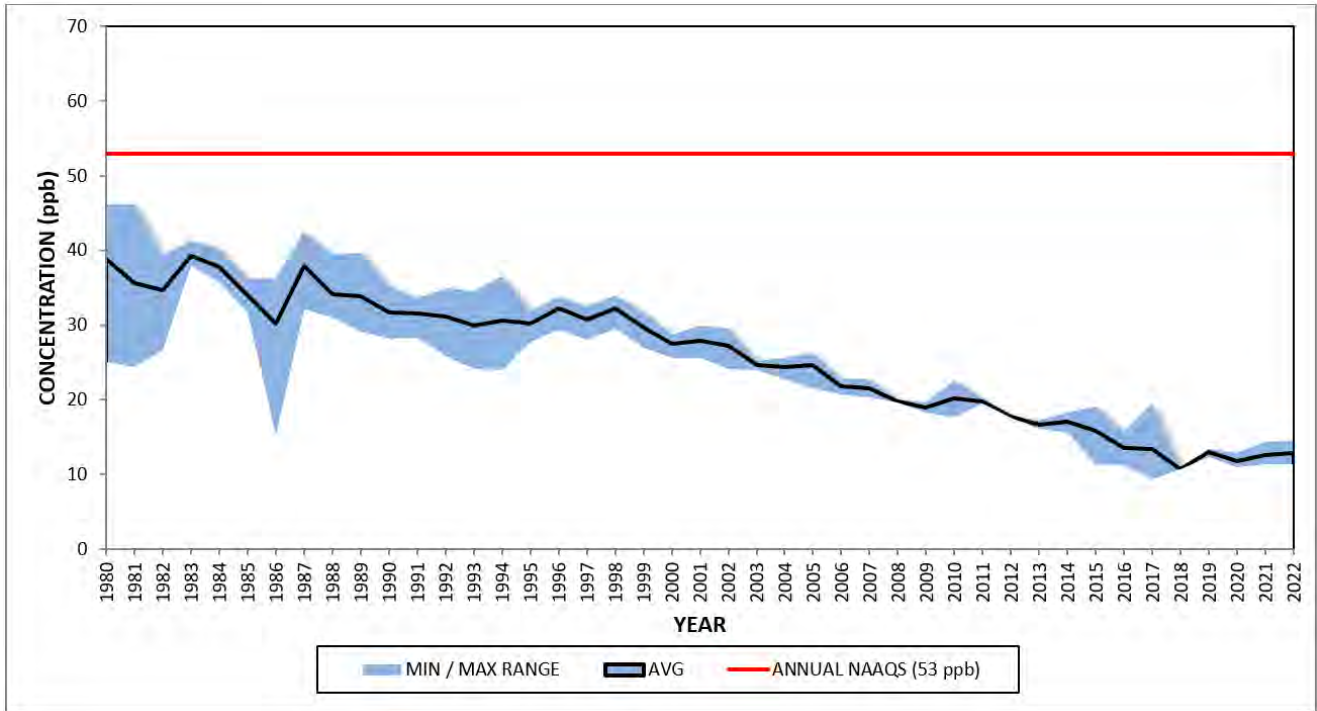

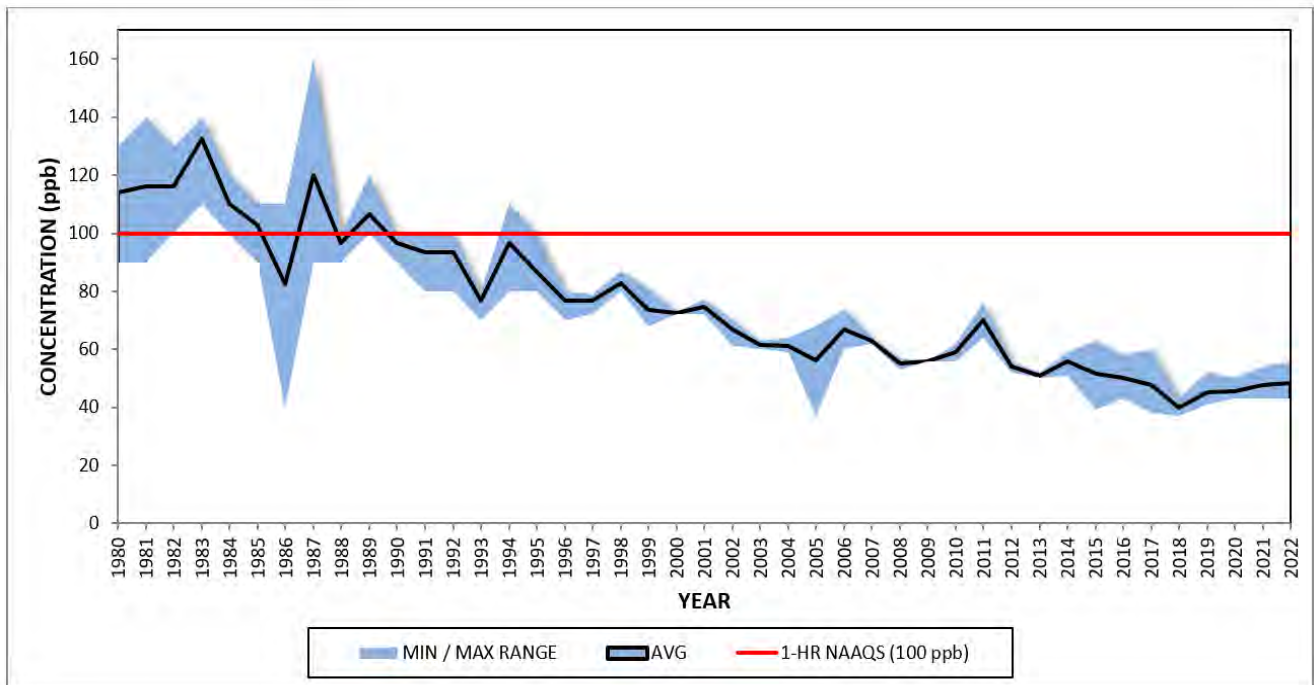

Figure 6.3 – NO₂ Trends for 98th Percentile Daily Maximum 1-Hour Concentration

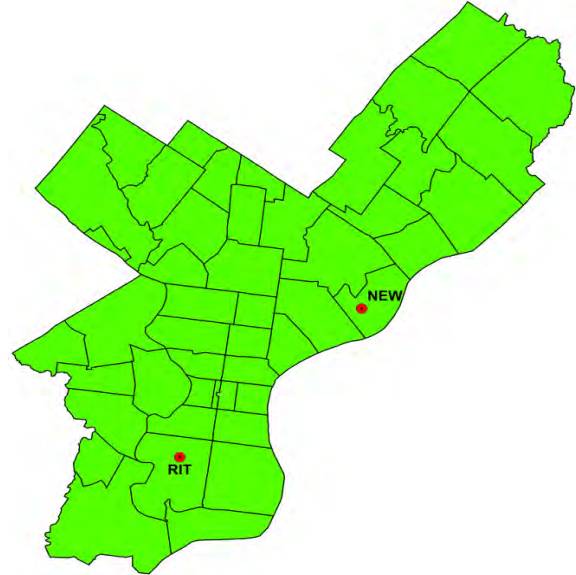

Sulfur Dioxide (SO₂)

NAAQS:

- The 3-year average of the annual 99th percentile of the daily maximum 1-hour average concentrations is less than or equal to 75 ppb.

Figure 7.1 – SO₂ Monitoring Map

Sulfur dioxide is emitted from the burning of fuels that contain sulfur. Industrial grade fuel oils are the primary source in Philadelphia.

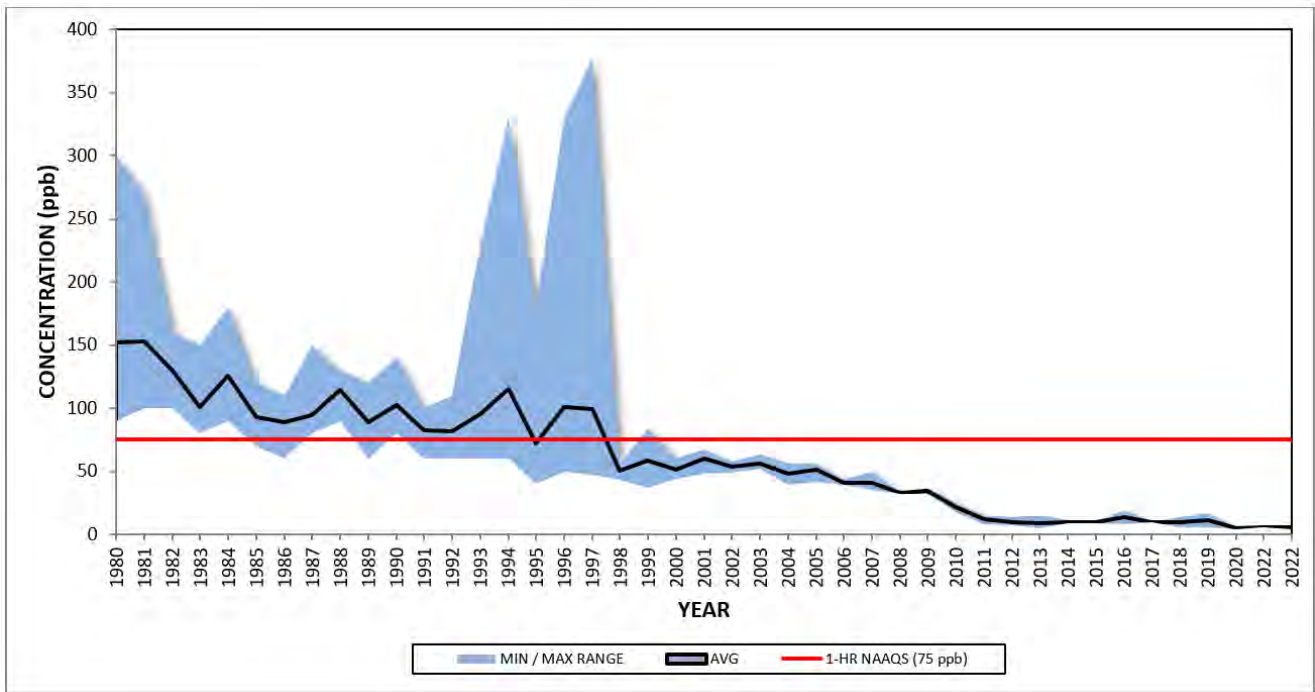

The major health concerns associated with exposure to high concentrations of SO₂ include effects on breathing, respiratory illness, alterations in the lungs' defenses, and aggravation of existing respiratory and cardiovascular disease. Together, SO₂ and NO_x are the major ingredients of acid rain. SO₂ also plays a significant role in the formation of fine particulate matter.

SO₂ levels in Philadelphia are well within air quality standards and show a slow, continued improvement over time. This is mainly due to industry, businesses, and homes changing to fuels with lower sulfur content such as natural gas.

In 2022, the NEW and RIT sites were operating as the monitoring sites for SO₂ as seen in Figure 7.1.

The following graph, Figure 7.2, shows the trends for the one-hour SO₂ concentration for Philadelphia.

Figure 7.2 – SO₂ Trends for 99th Percentile Daily Maximum 1-Hour Average Concentration

Lead (Pb)

NAAQS:

- The maximum arithmetic rolling 3-month mean concentration for a 3-year period is less than or equal to 0.15 $\mu\text{g}/\text{m}^3$ micrograms per cubic meter.

The processing of metals is the major source of lead emissions to the atmosphere. Lead does not travel over great distances in the air and so concentrations vary, with the highest levels near specific industrial sites.

Lead is a metal that is highly toxic when inhaled or ingested. Lead accumulates in the blood, bone, and soft tissue and may affect the kidneys, liver, nervous system, and other organs. It also can cause learning difficulties in children.

Ambient lead levels have been decreasing throughout the city due to the elimination of leaded gasoline and greater control of emissions from companies that produce, or process lead compounds.

Prior to 1998, lead levels in certain parts of the city were once extremely high due to the concentration of industries in the areas near Castor and Delaware Avenues. The levels of lead in these areas have drastically improved and are now comparable to the rest of the city.

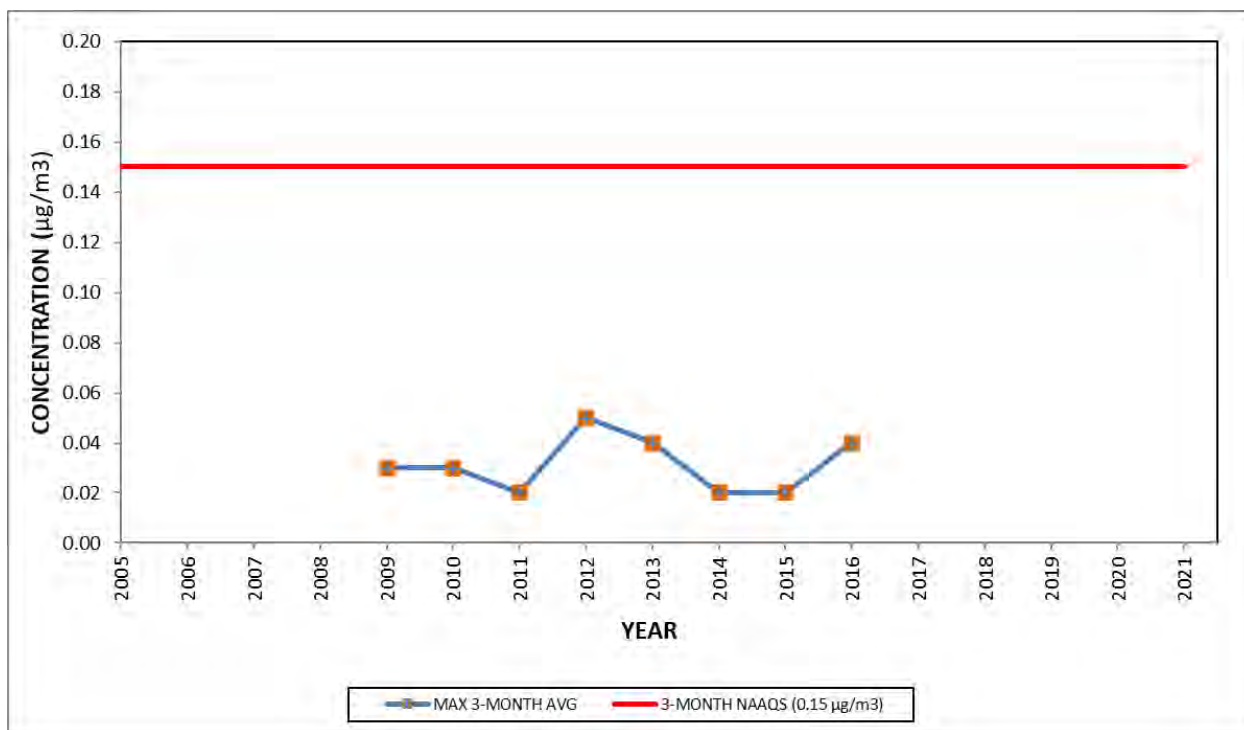

On October 15, 2008, the EPA strengthened its regulation for lead. The standard was revised from the 1978 standard of 1.5 $\mu\text{g}/\text{m}^3$ to a level that is 10 times more stringent, 0.15 $\mu\text{g}/\text{m}^3$, with a different averaging time. For the previous standard, the averaging time used a quarterly average while the new standard uses a rolling 3-month average. The revision is based on more than 6000 studies performed since 1990 on the health effects of high lead concentrations in the bloodstream. The studies show that adverse effects

from lead in the blood occur at a much lower level than previously thought. Figure 8.1 shows the trends for the 2008 lead standard.

As of January 1, 2017, Total Suspended Particulate Lead monitor was shutdown at NEW site. Philadelphia has no sources that emit 0.5 or more tons of Pb per year.

On 4/28/2017, EPA approved Philadelphia AMS' waiver of the requirement for a source-oriented Lead-TSP monitor in Philadelphia effective 1/1/17.

Figure 8.1 – Lead Trends (Maximum) Rolling 3-Month Average

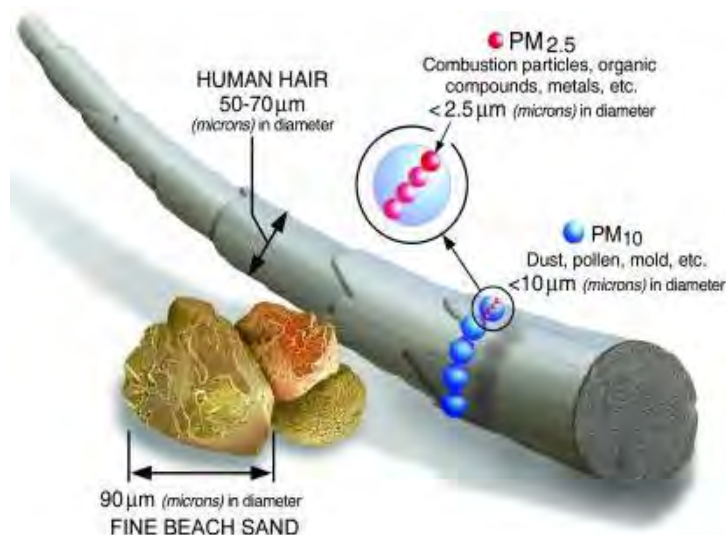

Particulate Matter (PM₁₀, PM_{2.5})

Particulate matter is the general term used for a mixture of solid particles and liquid droplets found in the air. These particles come in a wide range of sizes and originate from stationary, mobile, and natural sources.

Figure 9.1 – Size Comparisons for PM Particles

PM₁₀ and PM_{2.5} refer to small particulates that measure less than 10 micrometers (0.00001 meters) and 2.5 micrometers (0.0000025 meters) in diameter, respectively. In addition to health problems, particulate matter can cause reduced visibility, soiling, and damage to materials such as buildings. Particles of this size remain airborne for long periods of time and disperse in uniform concentrations across wide areas, crossing geographic boundaries⁹.

In 1997, the EPA set a separate standard for PM_{2.5}. Particles in the PM_{2.5} size range can travel deeply into the respiratory tract, reaching the lungs. Exposure to fine particles can cause short-term health effects such as eye, nose, throat, and lung irritation, coughing, sneezing, runny nose, and shortness of breath. Exposure to fine particles can also affect lung function and worsen medical conditions such as asthma and heart disease. Scientific studies have linked increases in daily PM_{2.5} exposure with increased respiratory and cardiovascular hospital admissions, emergency department visits and deaths. Recent studies suggest that long term exposure to particulate matter may be associated with increased rates of bronchitis and reduced lung function.

Particles come in a wide variety of shapes and sizes, which affect their impacts on human health and the environment. Bigger particles, such as dust, are easier to see and can cause problems, but smaller particles are likely to be worse for our health.

Fine particles are treated as though they are a single pollutant, but fine particles come from many different sources and are composed of many different compounds. Fortunately, these compounds fall into a few dominant categories: sulfates, nitrates, ammonium compounds, soil, organic carbon compounds, and elemental carbon. Water is nearly always an important and variable part of PM, and sea salt is often significant near the coast. Given the complex composition of PM, it is no surprise that its chemistry is also complex. Particles may be dry or wet. When the wind blows hard enough, soil, silt, and sand can be lifted from the surface. Human activities such as mining, construction,

⁹ EPA: www.epa.gov/pm-pollution/particulate-matter-pm-basics#PM

plowing, and driving on unpaved roads also lift particles into the air. Soot, also referred to as black carbon or elemental carbon, is emitted directly by diesel engines and forest fires, among other sources. Most individual particles are likely mixtures of different substances, the products of growing by collisions with other particles and by taking on gases.

PM₁₀

NAAQS:

- 150 µg/m³ for a daily 24-hour average concentration not to be exceeded more than once per year on average over a 3-year period.

Figure 10.1 – PM₁₀ Monitoring Map

Particulate matter levels have been decreasing due to regulations limiting the amount of emissions allowed and the change to cleaner fuels, for example, switching from oil to natural gas by industry, businesses, and homes.

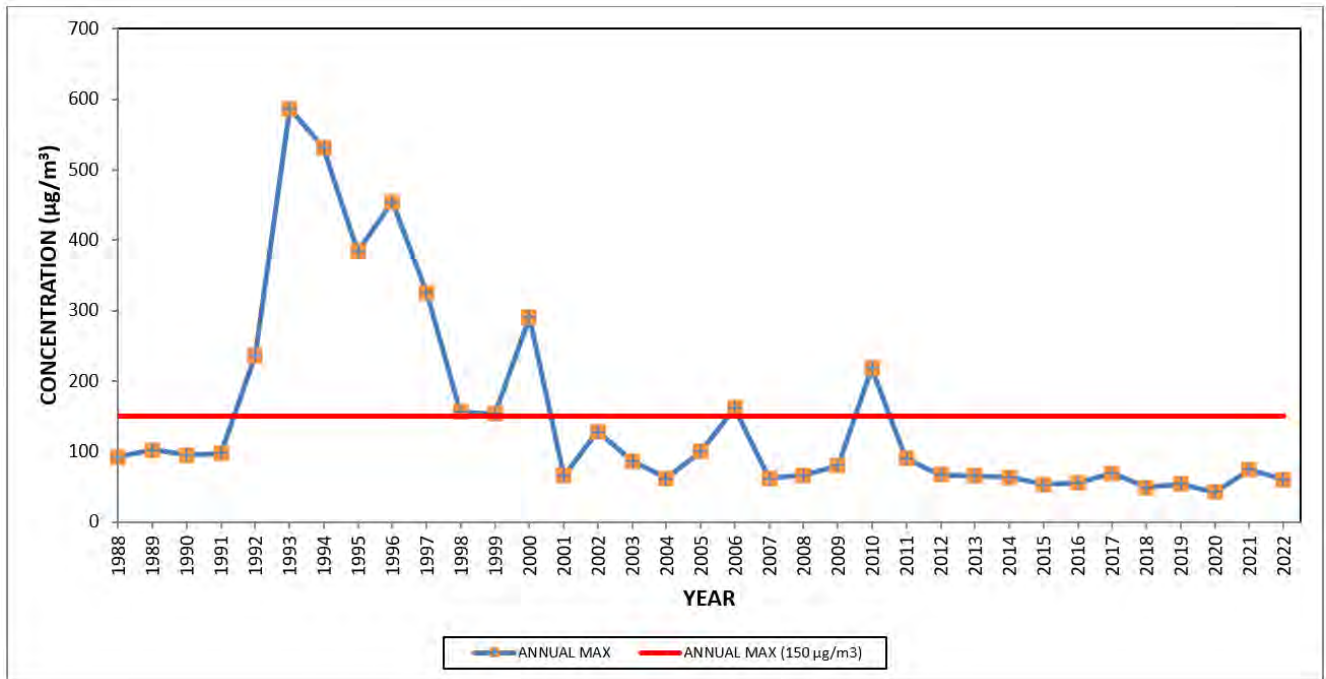

During the mid-1990s, particulate emissions from several sources around Castor and Delaware Avenues caused extremely high-localized measurements and the levels were many times higher than those measured at other city locations. Specific actions to abate these sources have resulted in air quality that now meets the national standards and are now comparable to levels in the rest of the city.

The EPA revoked the annual standard for PM₁₀ on December 17, 2006, due to a lack of evidence linking health problems to long-term exposure to coarse particle pollution.

As seen in Figure 10.1, there is one PM₁₀ monitoring site, NEW.

Figure 10.2 shows the trends for PM₁₀ for the maximum 24-hour average concentration in the city.

Figure 10.2 – PM₁₀ Trends for the Highest 24-Hour Average Concentration for All Monitoring Sites

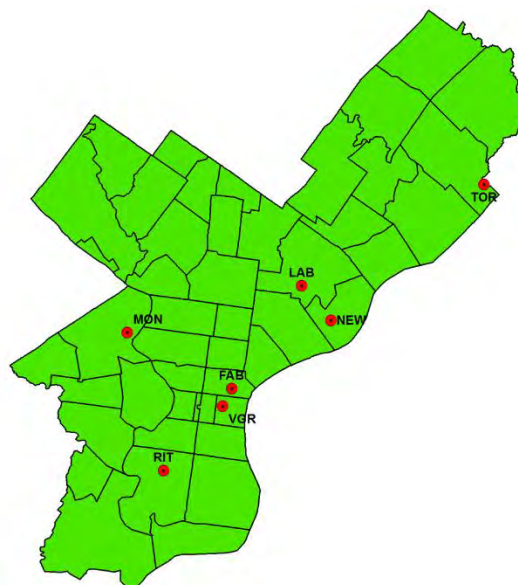

PM_{2.5}

NAAQS:

- The 3-year average of the annual arithmetic mean concentration is less than or equal to 12.0 µg/m³.
- The 3-year average of the 98th percentile 24-hour concentration is less than or equal to 35 µg/m³.

Figure 11.1 – PM_{2.5} Monitoring Map

PM_{2.5} consists of those particles that are less than 2.5 micrometers in diameter. They are also referred to as "fine" particles. Fine particles result from fuel combustion from motor vehicles, power generation, and industrial facilities, as well as from residential fireplaces and wood stoves. A significant amount of fine particles are also formed in the atmosphere by the transformation of gaseous emissions such as SO₂, NO_x, VOCs, and ammonia.

Fine particles can accumulate in the respiratory system and are associated with numerous health effects such as premature death, respiratory symptoms and disease, and decreased lung function. Sensitive groups that appear to be at the greatest risk for such effects include children, seniors, and individuals with cardiopulmonary disease or respiratory ailments such as asthma.

In 2022, there were seven PM_{2.5} monitoring sites in the network. Data from the VGR site is not used for comparison with the NAAQS.

Figures 11.2 and 11.3 show the trends for the 24-hour concentration and the annual mean, respectively.

Figure 11.2 – PM_{2.5} Trends for 98th Percentile 24-Hour Concentration

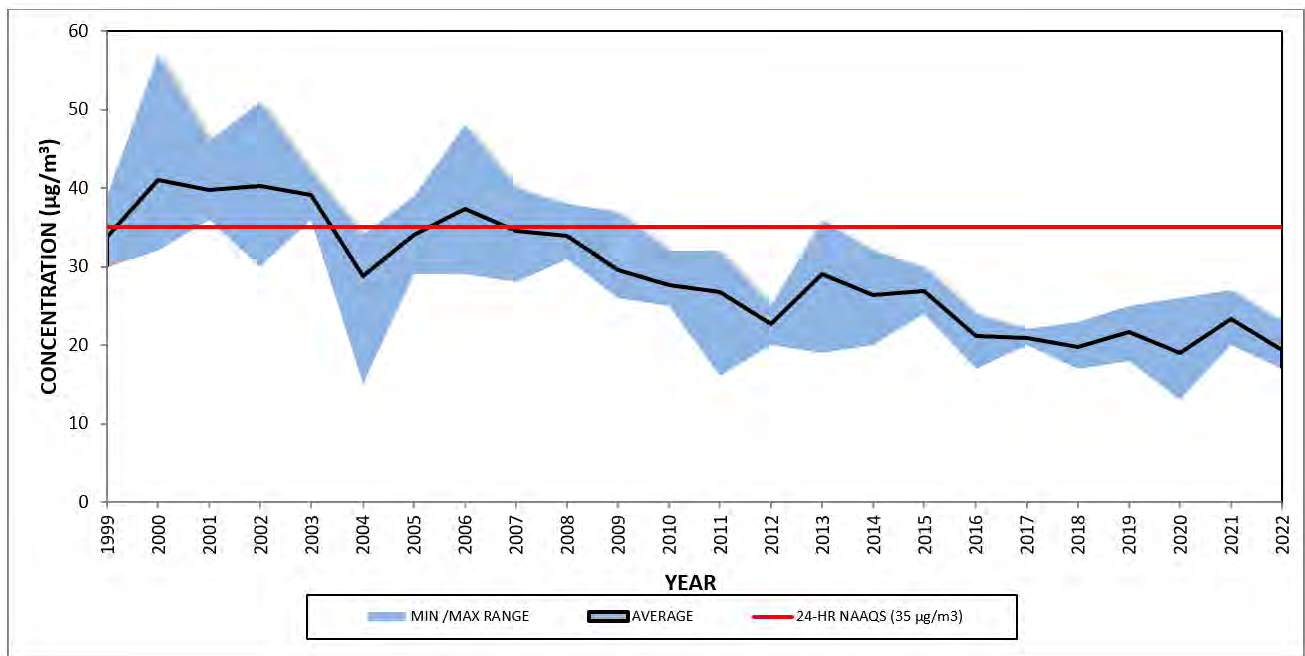

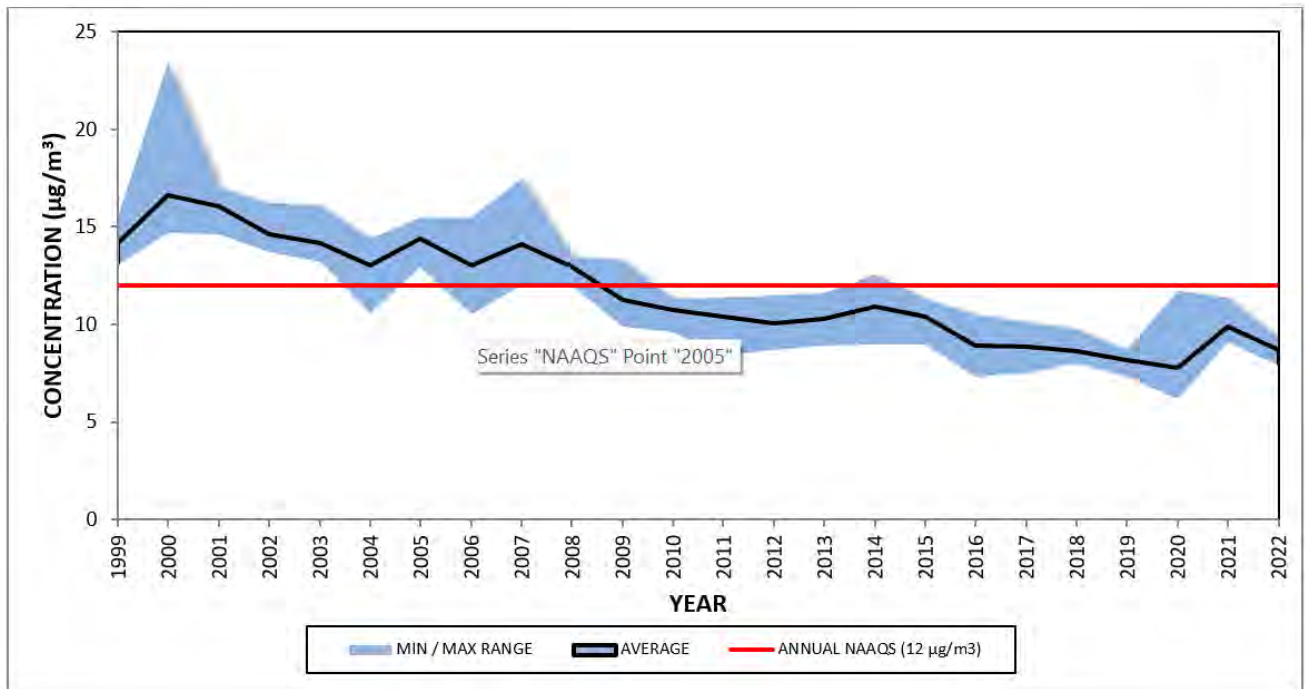

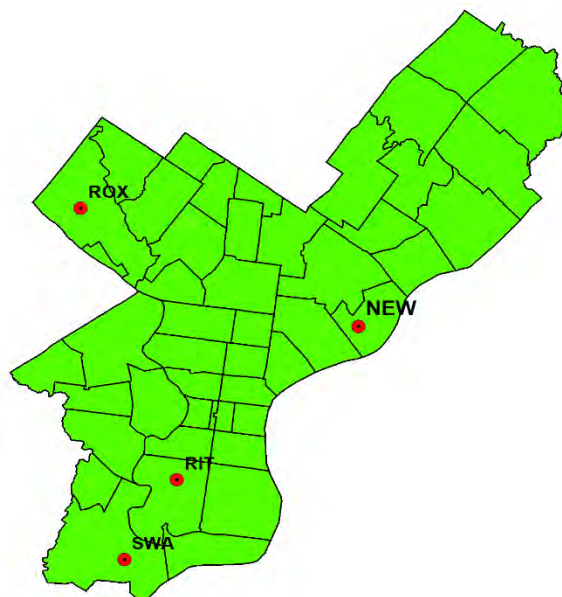

Figure 11.3 – PM_{2.5} Trends for Annual Mean Concentration

Air Toxics

Air toxics, also referred to as toxic air contaminants or hazardous air pollutants (HAPs), are substances that cause adverse health effects or environmental damage. The Federal Clean Air Act Amendments (CAAA) of 1990 list 188 pollutants or chemical groups as HAPs. Examples of air toxics include heavy metals (such as beryllium), organic chemicals (such as formaldehyde), polycyclic organic matter (POM, which are formed primarily by combustion), benzene (which is found in gasoline), pesticides, and asbestos. HAPs are emitted from stationary sources (large industrial facilities), nonpoint sources (dry cleaners, gas stations, and other small facilities), as well as mobile sources (cars, trucks and buses).

Figure 12.1 – Air Toxics Monitoring Map

In 2022, AMS monitored air toxics at 4 locations as seen in Figure 12.1. AMS monitors approximately 61 VOCs, 7 carbonyl compounds, and 59 hydrocarbons. Three different sampling methods are employed to obtain their concentrations in ambient air. VOCs are collected in 6-liter stainless steel canisters every six days and analyzed via Gas Chromatography/Mass Spectrometry. The carbonyls are also collected every six days on a cartridge and analyzed using an Ultra High Performance Liquid Chromatograph. The hydrocarbons are collected and analyzed hourly every day via auto-Gas Chromatography.

There is less information known about the health impact from the 188 HAPs than there are for criteria pollutants, and no national ambient air quality standards exist for them. However, a number of these pollutants are known or suspected to be carcinogenic, and there is no known “safe concentration.” The danger posed by toxics is often referred to in terms of risk. Risk is defined as the likelihood of a negative outcome from a certain level of a specific chemical, or the measure of a chance that health problems will occur. For example, many toxics cause cancer, while others cause respiratory problems, birth defects, neurological or immune response problems, and other health concerns. Toxics have varying degrees of danger, and some will cause harm with a very small amount of the substance while others require large amounts to have a negative effect. A cancer risk level of “one in a million” implies a likelihood that up to one person out of one million equally exposed people would contract cancer if exposed continuously (24 hours per day) to the specific concentration over 70 years (an assumed lifetime). This risk is calculated as additional (or incremental) to those cancer cases that would usually occur in an unexposed population of one million people.

AMS is helping to reduce HAPs in Philadelphia by enforcing Federal, State, and locally mandated programs that limit emissions from stationary and area sources. Many toxic emissions have been reduced by regulations designed to bring Philadelphia into compliance with the NAAQS for Ozone. In addition, Philadelphia enforces the National Emission Standards for Hazardous Air Pollutants (NESHAPs), a program designed to reduce emissions from existing major and area sources, as well as New Source Performance Standards (NSPS), which limit toxic emissions from new sources. In 2010, Air Management Regulation XIV – Control of Emissions from Dry Cleaning Facilities was promulgated. This regulation restricted the use of perchloroethylene (PERC) in dry cleaning facilities that share a common wall with businesses or residences. Since 2010, ambient concentrations of PERC have been decreasing.

Air Management Regulation VI is Philadelphia's local regulation for control of emissions of various air toxics. This regulation was being amended to further strengthen it in 2022.

In addition, AMS is currently working with other City departments to enforce Mayor's Executive Order 1-07 which requires all public works and demolition contracts to use clean diesel technology. This program is expected to significantly reduce particulate matter, hydrocarbons, and carbon monoxide from diesel vehicles contracted by the City, resulting in substantial annual health benefits.

The EPA's Air Toxics Screening Assessment (AirToxScreen) is a screening tool to provide communities with information about health risks from air toxics. AirToxScreen is EPA's ongoing comprehensive evaluation of air toxics in the U.S. The activities include expansion of air toxics monitoring, improving and periodically updating emission inventories, improving national- and local-scale modeling, continued research on health effects and exposures to both ambient and indoor air, and improvement of assessment tools. The latest version of the tool is the 2019 AirToxScreen. Air toxics were assessed for either lifetime cancer risk or non-cancer hazard due to inhalation at census tract level.

The goal of AirToxScreen is to identify air toxics which are of greatest potential concern, in terms of contribution to population risk. The results are used to establish strategies, priorities, and programs to reduce air toxics emissions.

The results of the 2019 AirToxScreen for Philadelphia County are summarized below:

- Total air toxics cancer risk was approximately 30 in one million population.
- By source category, secondary formation accounted for 45.8% of cancer risk and onroad mobile sources accounted for 11.3%. Point sources accounted for just 4% (see Figure 12.2).
- The pollutants contributing most to cancer risk were formaldehyde (52.5%), carbon tetrachloride (10.7%), and benzene (10.5%) (see Figure 12.3).

Figure 12.2 – Source Category Contribution to 2019 AirToxScreen Cancer Risk

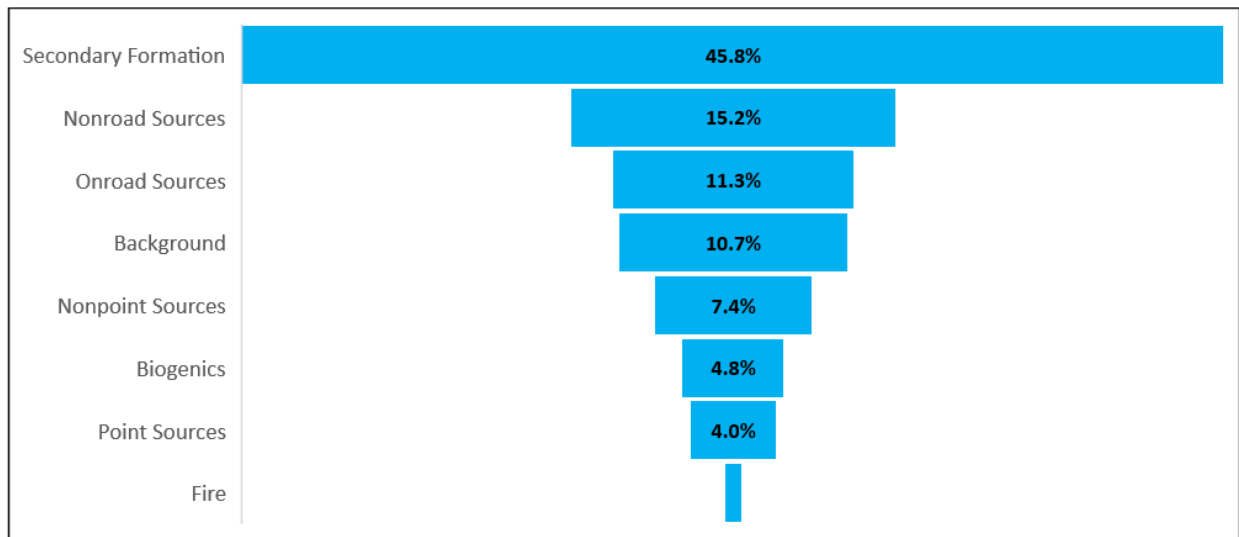

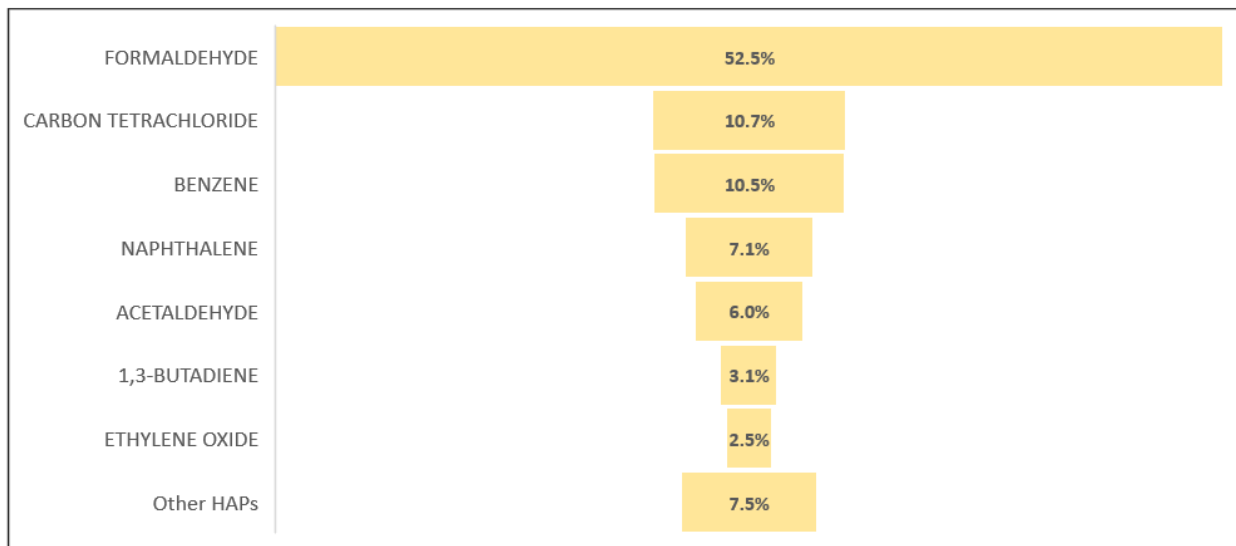

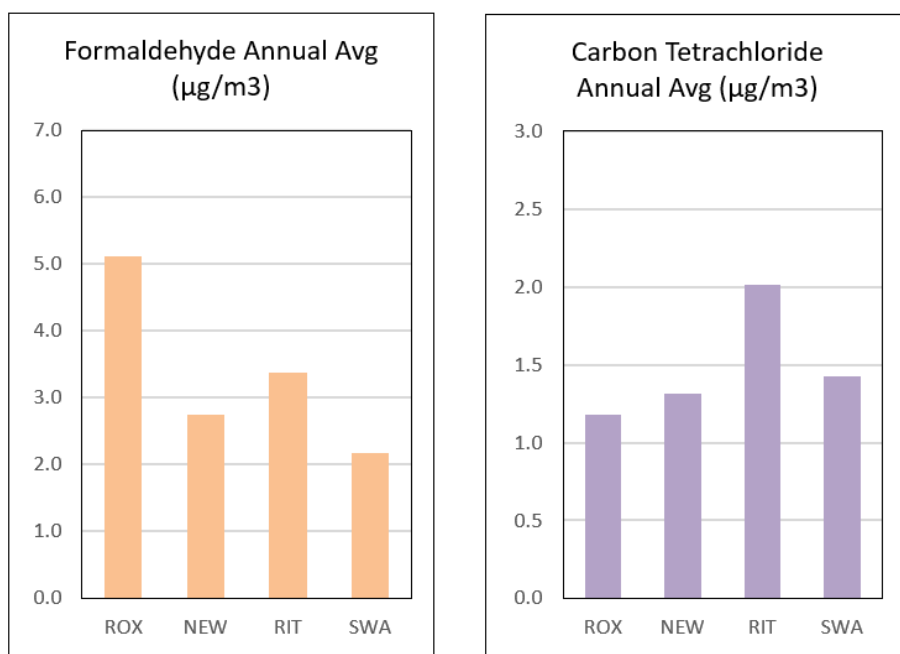

Figure 12.3 – HAP Contributions to 2019 AirToxScreen Cancer Risk

Addition information for the 2019 EPA AirToxScreen can be found here:
<https://www.epa.gov/AirToxScreen/2019-airtoxscreen-assessment-results#nationwide>

Figure 12.4 shows the 2022 annual mean concentrations for formaldehyde and carbon tetrachloride measured by AMS at four monitoring sites (ROX, NEW, RIT, and SWA). These two HAPs had the highest contribution to air toxics cancer risk in Philadelphia according to the 2019 AirToxScreen assessment.

Figure 12.4 – 2022 Mean Concentrations for Formaldehyde and Carbon Tetrachloride

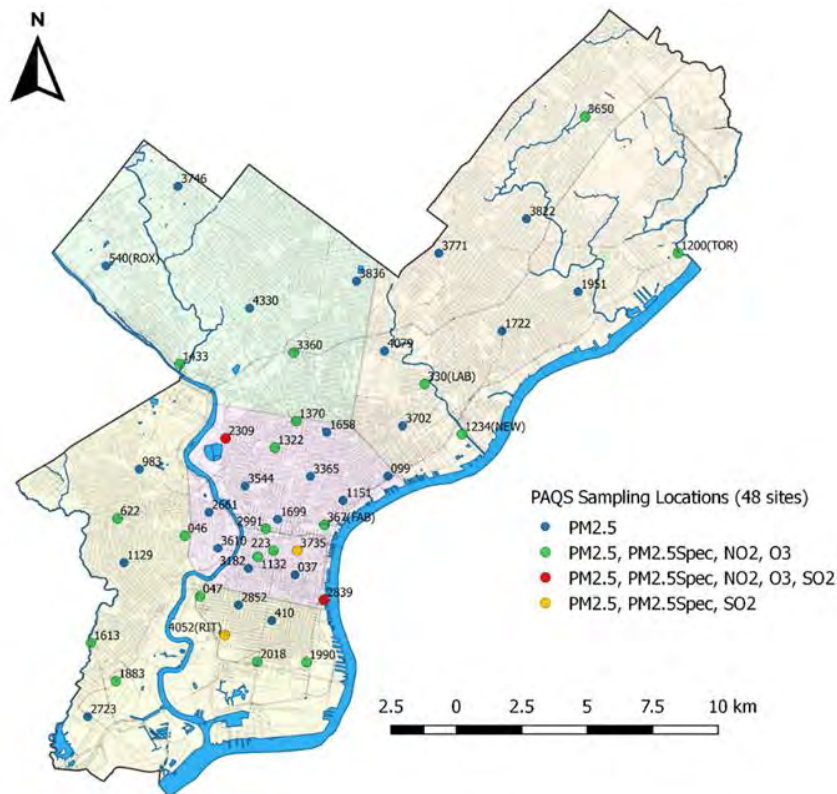

Data for air toxics can be found on the EPA websites <https://www.epa.gov/outdoor-air-quality-data/monitor-values-report-hazardous-air-pollutants> or https://aqs.epa.gov/aqsweb/airdata/download_files.html.

Philadelphia Air Quality Survey

In 2022, AMS continued to collect monitoring data from the Philadelphia Air Quality Survey (PAQS). Initially this project set up 50 street level, neighborhood-oriented air sampling sites throughout the City to measure the ambient air for PM_{2.5}, NO₂, SO₂, and O₃. Field sampling started in May 2018. The samplers also contain meteorological sensors. Minor adjustments to site locations were made in 2019; currently 48 sampling sites are maintained, as shown in Figure 13.1. PAQS captures seasonal changes and neighborhood-to-neighborhood spatial variances in air quality. The data results may serve as a basis for future work, including: providing policy recommendations for reducing pollution from congested traffic, diesel vehicles and wintertime fuel burning; analyzing the relations between air quality and land use characteristics in different neighborhoods; and studying public health impact of air pollution in the City. By the end of 2022, this project completed 73 two-week sampling sessions. For the period from December 1, 2021 through November 30, 2022, the highest 12-month average PM_{2.5} concentration was 9.3 µg/m³, which occurred at a site in Center City; the Citywide all-sites PM_{2.5} average concentration was 7.9 µg/m³ (the EPA annual standard is 12 µg/m³). Additional information regarding PAQS is provided in the latest version of the Philadelphia Air Monitoring Network Plan and the PAQS project report (<https://www.phila.gov/documents/air-management-reports-and-documents/>).

Appendix C: History of the National Ambient Air Quality Standard

Table 13 – History of the National Ambient Air Quality Standards for Carbon Monoxide¹¹

Final Rule/Decision	Primary/Secondary	Indicator	Averaging Time	Level	Form
1971 36 FR 8186 Apr 30, 1971	Primary and Secondary	CO	1-Hour period	35 ppm	Maximum, not to be exceeded more than once in a year ¹²
			8-hour period	9 ppm	Maximum, not to be exceeded more than once in a year
1985 50 FR 37484 Sept 13, 1985	Primary standards retained, without revision; secondary standards revoked.				
1994 59 FR 38906 Aug 1, 1994	Primary standards retained, without revision.				
2011 76 FR 54294 Aug 31, 2011	Primary standards retained, without revision.				

¹¹ <https://www.epa.gov/co-pollution/table-historical-carbon-monoxide-co-national-ambient-air-quality-standards-naaqs>

¹² Second highest, non-overlapping 8-hour average concentration.

Table 14 – History of the NAAQS for Pb-TSP (Lead in total suspended particles)¹³

Final Rule/Decision	Primary/Secondary	Indicator	Averaging Time	Level	Form
1978 43 FR 46246 Oct 5, 1978	Primary and Secondary	Pb-TSP	Calendar Quarter	1.5 µg/m ³	Not to be exceeded
1991	Agency released multimedia " Strategy for Reducing Lead Exposures "				
2008 73 FR 66964 Nov 12, 2008	Primary and Secondary	Pb-TSP	3-month period	0.15 µg/m ³	Not to be exceeded
2016 81 FR 71906 Oct 18, 2016	Primary and secondary standards retained, without revision.				

¹³ <https://www.epa.gov/lead-air-pollution/table-historical-lead-pb-national-ambient-air-quality-standards-naaqs>

Table 15 – History of the NAAQS for Nitrogen Dioxide¹⁴

Final Rule/Decision	Primary/Secondary	Indicator	Averaging Time	Level	Form
1971 36 FR 8186 Apr 30, 1971	Primary and Secondary	NO ₂	Annual	53 ppb ¹⁵	Annual arithmetic average
1985 50 FR 25532 Jun 19, 1985	Primary and secondary NO ₂ standards retained, without revision.				
1996 61 FR 52852 Oct 8, 1996	Primary and secondary NO ₂ standards retained, without revision.				
2010 75 FR 6474 Feb 9, 2010	Primary	NO ₂	1 hour	100 ppb	98th percentile, 1-hour daily maximum, averaged over 3 years ¹⁶
		Primary annual NO ₂ standard retained, without revision.			
2012 77 FR 20218 April 3, 2012	Secondary	Existing secondary NO ₂ standard (annual) retained, without revision.			
2018 83 FR 17226 April 18, 2018	Primary	Existing primary NO ₂ standards retained, without revision.			

¹⁴ <https://www.epa.gov/no2-pollution/table-historical-nitrogen-dioxide-national-ambient-air-quality-standards-naags>

¹⁵ The official level of the annual NO₂ standard is 0.053 ppm, equal to 53 ppb, which is shown here for the purpose of clearer comparison to the 1-hour standard.

¹⁶ The form of the 1-hour standard is the 3-year average of the 98th percentile of the yearly distribution of 1-hour daily maximum NO₂ concentrations.

Table 16 – History of the NAAQS for Ozone¹⁷

Final Rule/Decision	Primary/Secondary	Indicator	Averaging Time	Level	Form
1971 36 FR 8186 Apr 30, 1971	Primary and Secondary	Total photochemical oxidants	1 hour	0.08 ppm	Not to be exceeded more than one hour per year
1979 44 FR 8202 Feb 8, 1979	Primary and Secondary	O ₃	1 hour	0.12 ppm	Attainment is defined when the expected number of days per calendar year, with maximum hourly average concentration greater than 0.12 ppm, is equal to or less than 1
1993 58 FR 13008 Mar 9, 1993	EPA decided that revisions to the standards were not warranted at the time				
1997 62 FR 38856 Jul 18, 1997	Primary and Secondary	O ₃	8 hours	0.08 ppm	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years
2008 73 FR 16483 Mar 27, 2008	Primary and Secondary	O ₃	8 hours	0.075 ppm	Annual fourth-highest daily maximum 8-hr concentration, averaged over 3 years
2015 80 FR 65292 Oct 26, 2015	Primary and Secondary	O ₃	8 hours	0.070 ppm	Annual fourth-highest daily maximum 8-hour average concentration, averaged over 3 years

¹⁷ <https://www.epa.gov/ozone-pollution/table-historical-ozone-national-ambient-air-quality-standards-naaqs>

Table 17 – History of the NAAQS for Particulate Matter¹⁸

Final Rule/Decision	Primary/Secondary	Indicator¹⁹	Averaging Time	Level	Form
1971 36 FR 8186 Apr 30, 1971	Primary	TSP	24 hour	260 µg/m ³	Not to be exceeded more than once per year
1971 36 FR 8186 Apr 30, 1971	Primary	TSP	Annual	75 µg/m ³	Annual geometric mean
1971 36 FR 8186 Apr 30, 1971	Secondary	TSP	24 hour	150 µg/m ³	Not to be exceeded more than once per year
1971 36 FR 8186 Apr 30, 1971	Secondary	TSP	Annual	60 µg/m ³	Annual geometric mean
1987 52 FR 24634 Jul 1, 1987	Primary and Secondary	PM ₁₀	24 hour	150 µg/m ³	Not to be exceeded more than once per year on average over a 3-year period
1987 52 FR 24634 Jul 1, 1987	Primary and Secondary	PM ₁₀	Annual	50 µg/m ³	Annual arithmetic mean, averaged over 3 years
1997 62 FR 38652 Jul 18, 1997	Primary and Secondary	PM _{2.5}	24 hour	65 µg/m ³	98th percentile, averaged over 3 years
1997 62 FR 38652 Jul 18, 1997	Primary and Secondary	PM _{2.5}	Annual	15.0 µg/m ³	Annual arithmetic mean, averaged over 3 years ^{3,4}
1997 62 FR 38652 Jul 18, 1997	Primary and Secondary	PM ₁₀	24 hour	150 µg/m ³	Initially promulgated 99th percentile, averaged over 3 years; when 1997 standards for PM ₁₀ were vacated, the form of 1987 standards remained in place (not to be exceeded more than once per year)
